This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1920 Excerpt: ...artery its walls are, in a few places, almost deficient. Whether its posterior end is open or really closed off is very difficult to determine. Beyond the latter point a few scattered but conspicuous cells are found, quite different from the other cells near them, especially as regards their larger, longer, and more deeply staining processes. They are to be looked upon as material for the further growth and extension of the aorta or its branches. Situated in the line of the aorta and laterally toward the yolk-sac, these cells show the orientation described for similar cells in the cat by Schulte (1914), forecasting, as it were, the long series of vitelline arteries which is to follow. There are in addition, also at the posterior end of the aorta, indications of a very few short, mesially directed branches, not always closed off from the wide intercellular spaces adjoining, which represent the first dorsal rami of the aorta. The exact location of the vitelline artery can not be determined; continuing the segments backward would place it about the region of the sixth, the future third cervical. Felix places the anterior connection with the aorta at the seventh segment, in the stage of 5-6 somites, while in a 2.6 mm. embryo with 13-14 somites this connection has shifted back to the tenth segment on the right side and beyond the twelfth on the left. On the left side certain minor differences are to be observed. In the region of the somites the aorta is larger than on the right. This is followed by a short stretch where the vessel is possibly interrupted but represented, at least in part, by a solid chain of large cells. Its posterior end is enlarged like that on the right, but, instead of being open, is occupied by a small blood island (fig. 12). The conditions...
